# Sniper<sup>®</sup> Balloon Occlusion Microcatheter

Quick Guide

IMPORTANT! Always refer to the Sniper Balloon Occlusion Microcatheter Instructions For Use for detailed instructions.

## Contents

Limit input to no greater than 900 psi and 2 ml/second.

## EMBOLX

#### **Best Practices**

#### Imaging Before Embolization to Confirm Flow Redistribution

- When the catheter tip is at the desired location, complete an angiogram with the balloon down and with the balloon up.
- IMPORTANT! When the balloon is up, blood flow is slow and contrast will take longer to reach the tumor or prostate. Therefore, fluoroscopy timing will be longer for contrast visualization as compared to the balloon down configuration.

#### Slow Injection of Contrast and Embolic Agent

- Flow redistribution in favor of the tumor or prostate requires that a low pressure is maintained distal to the balloon.
- ► Slow injection is required to maintain low pressure.
- Rapid injection will overwhelm the protective pressure gradient.
- Contrast injection rate should be between 0.5 to 1.0 ml/second.
- Embolic injection rate should be about 1.0 ml/minute with intermittent pause between injections.

## Recommended Diagnostic Catheter Length with 110 cm Sniper

The use of a 65 cm diagnostic catheter is recommended for use with the Sniper 110 cm length as it maximizes the distal reach inside the patient.

#### **Reaching Embolization Endpoint**

With balloon occlusion there is slow moving, forward flow around the catheter tip due to reversal of collateral arteries, capillaries and interstitial fluid. Depending on Sniper tip placement during embolization, the treatment endpoint can be visualized under fluoroscopy as follows:

#### Sniper tip is subselective (Low Pressure Delivery)

 Observation of contrast stasis in distal arteries.

Sniper tip is superselective (High Pressure Delivery)

- Observation of:
- Contrast in portal vein **or**
- Embolic reflux around the Sniper balloon **or**
- Sniper balloon "pushing back" in the vessel.

#### Watershed Tumor Treatment

- Use high pressure delivery where the Sniper tip is placed superselectively or segmentally.
- Not Recommended: Low pressure delivery where the Sniper tip has a subselective or Lobar placement. In tumors that are between segments and have multiple feeders, a low pressure is maintained only in the segment with the balloon occlusion. Therefore, pressure from the feeders originating in the other segment with normal pressure can flow through the tumor and into the low pressure created by the occlusion.

## Troubleshooting

### **Kink Prevention**

#### Cause:

- An important part of Sniper's exceptional tracking ability is its stiff proximal catheter. The catheter can kink if the operator is not aware.
- There is a kink point at the RHV. The catheter cannot be bent sharply in this area.

#### Solution:

Advance the catheter forward by holding and pushing the catheter no more than 3 cm from the RHV.

#### **Unexpected Balloon Deflation**

#### Cause:

- The valve is either not connected or not sufficiently tightened to the balloon port or
- Excess vacuum in balloon lumen.
- Solution:
- When inflating balloon, connect syringe to the valve on balloon port.
- Remove and reconnect the valve on the balloon port which equilibrates the pressure.
- Re-inflate the balloon until it is seen contouring to the vessel wall under fluoroscopy.

#### **Balloon Migration**

#### Cause:

 A distal shift of the balloon is normal and expected and should be corrected.

#### Solution:

- ▶ Remove 25% of the balloon inflation volume.
- ▶ Retract the Sniper catheter, with the balloon 75% inflated, until the balloon is in the desired position.
- While holding the Sniper and diagnostic catheter in place, re-inflate the balloon until it is seen contouring to the vessel wall under fluoroscopy.

#### **Unable to Visualize Inflated Balloon**

10	7		
-	_	100	
<u> </u>		1	
· · · ·			

Insufficient amount of contrast in balloon.

- Cause: ► Insuffic Solution:
- ► Take a high resolution spot image **or**
- Disconnect 0.25 ml syringe and connect 10 ml syringe filled with 2 ml of 50% contrast. Pull syringe plunger to top lock position for 2 minutes. Move plunger slowly down onto contrast. Then reconnect 0.25 ml syringe to reinflate balloon.

## **Specifications and Compatibilities**

#### Specifications

Balloon Diameter	$Up \ to \ 6 \ mm \ \ \ \ (which \ occludes \ up \ to \ 5.5 \ mm \ vessels)$
Catheter Functional Length**	110 cm 130 cm 150 cm
Tip Shape <sup>**</sup>	Straight tip
Catheter Outer Diameter (proxima	al) 2.9F (0.038")
Catheter Outer Diameter (distal)	2.2F (0.029")
Catheter Inner Diameter (Infusion	Lumen) 0.020" (0.51 mm)
Dead Space Volume (hub + catheter)	0.32 ml (110 cm) 0.36 ml (130 cm) 0.41 ml (150 cm)
Injection Pressure	Up to 900 psi
Compatibilities	
Guidewire	0.014" or 0.016"
Embolic Beads‡	Up to 900 μm
Coils*	Up to 0.018"
Embolic Agents*	Lipiodol <sup>®</sup> , EtOH, DMSO, Y-90, Gelfoam, Glue (n-bCA)
